## The Functions Of Bipod

The animals that you hunt live in the middle of an abundance of rocks, trees, mounds and other rifles rest. Alas, there is never a rock or limb where you need it when you have little time to shoot. That's why the man invented a rest for his spear. Well, maybe the bipod does not go that far. But it has been used for a long time. The crossed sticks helped the snipers to strike at a distance prior to the advent of powder (smokeless).

Moneymaking hunters who clean up the plains of bison used them for murderous purposes. In the middle 1880s, the number was so great that human scavengers would be gleaning three million tons of meadow bones. Military and sports rifles are usually available with attached bipods. Widely praised, the Harris Bipod has been upgraded over the years with the addition of expandable legs. The new types also integrate some scope for tilt, as a result, you can rotate the rifle slightly to straighten it on a sloping terrain. This is a useful feature, even if the unit has adjustable feet.

There may be no time to lengthen or retract a leg or you cannot risk doing so for fear of getting attention. If there is some "rock" at the bipod base, it is important to note that you may twist the weapon enough to put it reasonably at the shoulder level. Set a bipod for a shot, choose a firm but impressionable surface on a hard. When you put your weapon on the bench rest, it is likely that you will get improved results with the feet of the bipod on the jacket or the soft ground that absorbs the vibrations caused by your pulse and the shock of the shot and the bullet in the bore. The vibration kills the balls of course. At a recent shooting event, we made consistent strikes on 500-yard pie targets with a rifle. While long-legged bipods can be used from the sitting position, most are designed for flat fire. We keep our legs as low as possible to pull comfortably.

A bipod should not put you in an awkward position. If it forces the head up or puts a sharp angle in the elbows, it is too high. You are smart, having planted bipod feet, to push in the rifle with your shoulder. The pressure on the bipod legs should sit them more firmly. Some light bipods give way to this pressure. To help a bipod, make the left hand in the first and place it under the stock feet shaking hands or relaxing your make slight changes in altitude. Another tip: buy or shape a small bag of sand, no bigger than a baseball, nonetheless brick-shaped, with a light load to hold under the butt.

This is an advantage if you have to bring the stock a little higher than your fist alone can comfortably boost it. The long-leg version of the attached bipod is a pair of shooting sticks. A standard kit for all professional hunters of long African grass, shooting sticks can be as simple

as shaved tree limbs tied by internal tube strips. More sophisticated versions, with telescopic quick-lock legs, have proliferated. If you are using a bipod or kneeling, keep your legs a little longer than you think you need. Push them forward when you have planted them, therefore they lean toward you.
